INTRODUCTION

The material presented in this volume (Vol. 3) of the technical documentation explains any special methodology used in the analyses for the final report describing the results of the 2005 California Tobacco Survey (CTS) (Al-Delaimy et al., 2006, 2007). While central to the analyses presented in the final report, this description would have detracted from a straightforward presentation of the survey results. Not every chapter included special analyses that needed to be described in the present volume.

Volume 1, Chapter 1 of the 2005 report uses several different national surveys to compare tobacco control progress in the US with that in the rest of the US. A brief description of the methodology for these national surveys is presented in this volume under Chapter 1.

A brief description of the 2005 CTS is presented in the introduction for Volume 1, Chapter 2 of the report, with a more detailed description in this volume in the section for the methods related to Chapter 2.

Volume 2, Chapter 4 of the report includes analyses on smoking in movies and uses data from a large Dartmouth database of smoking in movies, courtesy of James D. Sargent. A description of the methodology used is included.

Volumes 1 and 2 of the 2005 final report each included a glossary of terms describing smoking behavior or status. A complete glossary of the terms used in both volumes is included in this one as well.

Descriptive tables are also presented in this report.

Volume 1, Chapter 1

TOBACCO CONTROL PROGRESS IN CALIFORNIA AND THE REST OF THE U.S.

National Surveys Used to Compare California with the Rest of the US

Behavioral Risk Factor Surveillance System (BRFSS)

The Behavioral Risk Factor Surveillance System (BRFSS) was established in 1984 by the Centers for Disease Control and Prevention (CDC) and is a state-based system of health surveys that collects information on health risk behaviors, preventive health practices, and health care access primarily related to chronic disease and injury. For many states, the BRFSS is the only available source of timely, accurate data on health-related behaviors.

Currently, data are collected monthly in all 50 states, the District of Columbia, Puerto Rico, the U.S. Virgin Islands, and Guam. More than 350,000 adults are interviewed each year, making the BRFSS the largest telephone health survey in the world. States use BRFSS data to identify emerging health problems, establish and track health objectives, and develop and evaluate public health policies and programs. Many states also use BRFSS data to support health-related legislative efforts.

California Student Survey (CSS)

The California Student Survey (CSS) is a mandated statewide project, conducted since 1985. Every two years, the CSS presents a snapshot of students' risky and health-related behaviors, including drug, alcohol and tobacco use; resilience and perception of school violence.

The eighth CSS marked a major milestone when the sponsoring agencies determined in 1999 that the CSS should be expanded to provide data on a range of health-related behaviors that would be comparable with CDE's new California Health Kids Survey (CHKS). In addition to providing comparable state norms for the local CHKS, the CSS expansion had several other benefits, including reducing the number of different health surveys in the schools, enabling schools to combine participation in the CSS with their local collection of CHKS data, and expanding comparability of the CSS to the National Youth Risk Behavior Survey (YRBS). The result has been the creation of an integrated local and state health behavior data collection system that can serve the needs of multiple agencies and programs.

Tobacco Use Supplement to the Current Population Surveys (TUS-CPS)

The national Current Population Survey (CPS) periodically includes a special Tobacco Use Supplement (TUS), which was the source of the data for this analysis. The CPS is a continuous survey (over 56,000 households/month) conducted by the US Bureau of the Census, primarily to monitor labor force indicators for the civilian non-institutionalized US population age 15 years and older. The complete CPS methodology is published elsewhere (US Bureau of Labor Statistics and US Census Bureau, 2002). Briefly, the CPS includes a

probability sample, based on a stratified sampling scheme of clusters of four neighboring households identified from the most recent decennial census, updated building permits, and other sources. All strata are defined within state boundaries, and the sample is allocated among the states so that state-specific estimates can be computed. The TUS was developed by the National Cancer Institute staff and pre-tested by trained Bureau of the Census interviewers prior to implementation. The TUS is administered during three separate months at approximately three-year intervals.

TUS were included for 1992-1993, 1995-1996, 1998-1999, 2001-2 and 2003. For the analyses presented in this report, data on adults age 18 years and older from the three months in each period were analyzed.

National Health Interview Survey (NHIS)

The National Health Interview Survey (NHIS) is the principal source of information on the health of the civilian noninstitutionalized population of the United States and is one of the major data collection programs of the National Center for Health Statistics (NCHS). The National Health Survey Act of 1956 provided for a continuing survey and special studies to secure accurate and current statistical information on the amount, distribution, and effects of illness and disability in the United States and the services rendered for or because of such conditions. The survey referred to in the Act, now called the National Health Interview Survey, was initiated in July 1957. Since 1960, the survey has been conducted by NCHS, which was formed when the National Health Survey and the National Vital Statistics Division were combined.

NHIS data are used widely throughout the Department of Health and Human Services to monitor trends in illness and disability and to track progress toward achieving national health objectives. The data are also used by the public health research community for epidemiologic and policy analysis of such timely issues as characterizing those with various health problems, determining barriers to accessing and using appropriate health care, and evaluating Federal health programs.

Youth Risk Behavior Surveillance System (YRBS)

The YRBSS was developed in 1990 to monitor priority health risk behaviors that contribute markedly to the leading causes of death, disability, and social problems among youth and adults in the United States. The YRBSS was designed to determine the prevalence of health risk behaviors, assess whether health risk behaviors increase, decrease, or stay the same over time, examine the co-occurrence of health risk behaviors, provide comparable national, state, and local data, provide comparable data among subpopulations of youth, and monitor progress toward achieving the Healthy People 2010 objectives and other program indicators.

The YRBSS includes national, state, and local school-based surveys of representative samples of 9th through 12th grade students. These surveys are conducted every two years, usually during the spring semester. The national survey, conducted by CDC, provides data representative of high school students in public and private schools in the United States. The

state and local surveys, conducted by departments of health and education, provide data representative of public high school students in each state or local school district.

Per Capita Cigarette Consumption Trends

A description of how per capita cigarette consumption was determined was presented in Chapter 1 of the final report (Al-Delaimy et al., 2006), but is repeated here for completeness. Until late 1998 when it was disbanded, the Tobacco Institute compiled cigarette sales data on a monthly basis in each state for federal tax reporting purposes (The Tobacco Institute, 1997). Since then, the same group responsible for compiling the earlier data has been producing it through the economic consulting firm of Orzechowski and Walker, with support from the tobacco industry (Orzechowski & Walker, 2005).

As these data are from wholesale warehouse removals, variation from one month to the next is considerable; in particular, the levels of removals in the last month of any quarter are strongly correlated with the removals in the first month of the next quarter. This variation has little to do with actual consumption and likely reflects business practice. To partially remove this source of variation, data were combined into 2-month intervals with December/January, February/March, etc., treated as single intervals. To convert the sales data to per capita cigarette consumption, the mean number of packs removed from warehouses in each interval was divided by the total population of adults aged 18 years or older. Presently, these population figures are based on unrevised projections from the 1990 census for 1991-1999, and from the 2000 census for 2001-2005. Annual values are interpolated to obtain the populations for each 2-month interval.

Even after averaging the sales figures for December/January, February/March, etc., the plots show that enough periodicity remains that it is difficult to determine when there is a change in trend. Thus, to facilitate interpretation of the per capita consumption data, a special procedure was employed that first decomposes a univariate time series into a seasonal component, and an adjusted component from which the seasonal component is removed. Finally, it computes a smoothed or adjusted version of the trend. With the smoothing part of the procedure there are user-specified parameters for the smoother window and how to handle the beginning and end of the time series, which will not have a full window's worth of data for smoothing. The smoothed trend, therefore, is not always as representative of the trend at the tails as it is in the middle of the range. The procedure used is available in S-Plus as the SABL macro (MathSoft, 1999). In the regression models described below, the deseasonalized trend data were used.

Standardization of Adult Smoking Prevalence Estimates

When comparing trends in smoking prevalence in California to the trends in the rest of the United States, the differences in the demographic distributions for California and the rest of the United States need to be taken into account. California differs from many other areas in the country in its racial/ethnic composition, and perhaps by age and education as well.

For consistency with the standardization carried out in previous examinations of the trends in smoking prevalence (Gilpin et al., 2004), the following demographic categories were used: gender (male and female), age (18-29, 30-39, 40-49, 50-59, and 60+), race/ethnicity (White and Non-White), and education (some college and no college). This set of demographic categories yields $2 \times 5 \times 2 \times 2 = 40$ cells.

The cell population totals for the direct standardization procedure were from the sums of the weights for the various cells from the 2005 CTS screener survey. The population totals used to develop these weights were from the Current Population Survey annual demographic file of March 2005.

In the direct standardization procedure (Fleiss, 1981), weighted (using survey weights) prevalence is computed for the respondents in each of the 40 cells, and then the results are multiplied by the fraction that particular cell represents of the total population, and the results are summed over all 40 cells to obtain the standardized estimate.

Volume 1, Chapter 2

TRENDS IN TOBACCO USE IN CALIFORNIA

2005 Cross-Sectional CTS

The 2005 California Tobacco Survey (CTS) consisted of three surveys. First, as in previous CTS, a five-minute screener interview was conducted with a household adult. The screener respondent provided demographic information on all household residents, including smoking status. In addition, the screener respondent was asked about household smoking restrictions and household income. Based on the information from the screener, certain household residents were selected for extended interviews.

The design of the 2005 CTS was very similar to that of the 1990, 1992, 1999, and 2002 CTS (Gilpin et al., 2004). In 1993 and 1996, a short extended interview was conducted with the screener respondent. In 1993, because of lack of funds, that was the only adult interview conducted, and in 1996 the short interview with the screener respondent was retained (if the screener respondent was not selected for the longer extended interview), so that comparisons could be made with the 1993 CTS results. However, a comparison of results from the short and long interviews in 1996 showed that the estimates for the items included on each (the short interview was a subset of the longer interview) were nearly identical. For that reason, the 1999, 2002, and 2005 CTS design reverted to the earlier model employed in 1990 and 1992.

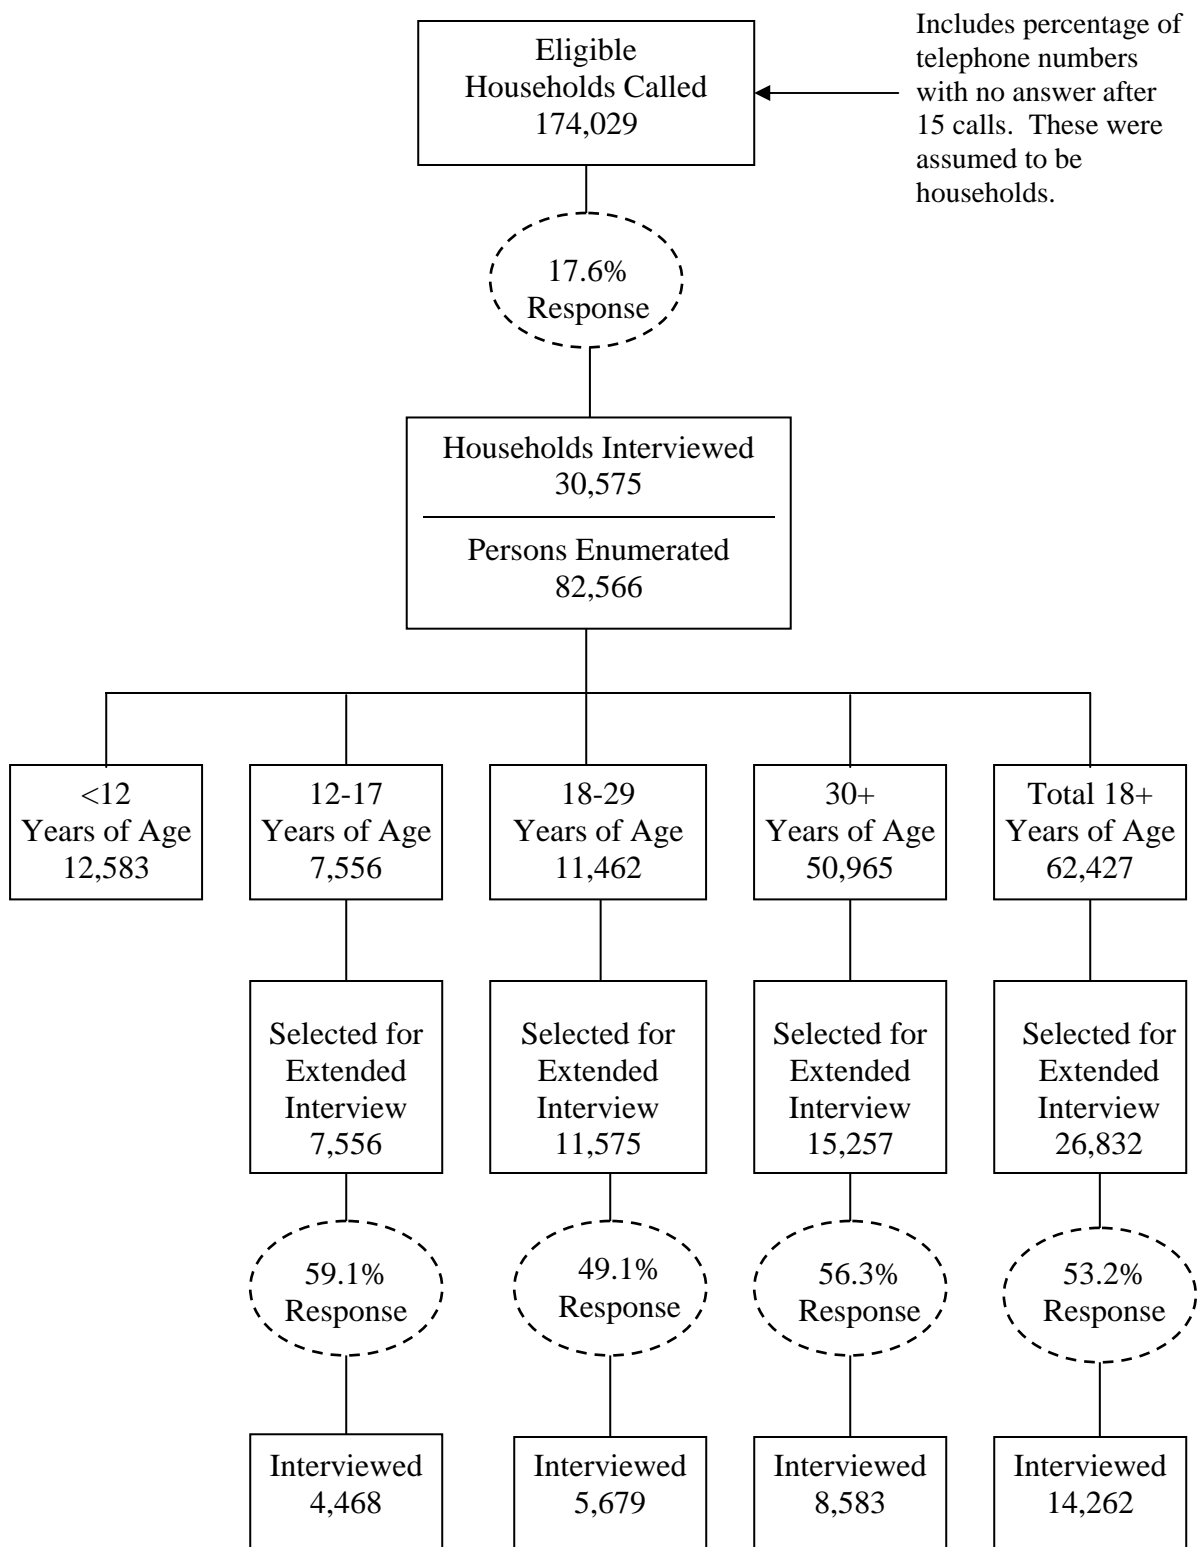

As in the earlier CTS, the probability of selection for an adult extended interview in 2005 was much higher if the person had been a smoker within the past five years. For a complete description of the sampling methodology both at the household and individual level see the survey technical documentation (Al-Delaimy et al., 2007a).

The 2005 CTS attempted to interview all adolescents in the household between 12 and 17 years, as in all other CTS except the 1999 CTS, which randomly selected just one adolescent.

The 2005 CTS selected all young adults between 18 and 29 years for an extended interview; this was initiated in the 2002 CTS. A special section of the adult interview was designed to capture young adult smoking behavior and attitudes.

Interviewers attempted to contact 174,029 households (see flowchart). The screener survey was completed for 30,575 (17.6%) of these selected telephone numbers. Of the 82,566 people enumerated in these households, 7,556 were between 12 and 17 years of age, and completed youth extended interviews were obtained for 4,468 (59.1%). Also, 11,575 persons between 18 and 29 years were enumerated, and completed extended interviews were obtained for 5,679. Finally, 50,965 adults age 30 years and older were enumerated. Of these 15,257 were selected for an extended interview based on their reported smoking status, and 8,583 completed the adult extended interview (56.3%). Details of the sampling methodology are in another technical report (Al-Delaimy et al., 2007b).

2005 California Tobacco Survey
FLOWCHART

Standardized Estimates of Adult Smoking Prevalence

As for the results presented in Chapter 1, the prevalence estimate trends from the CTS needed to be standardized so that trends could be compared over time.

All estimates were standardized by the distribution of the population totals for the demographic subgroups (see section on Chapter 1) obtained from the sums of the weights from the 2005 CTS screener survey. These reflect the population totals from the March 2005 Current Population Survey (CPS, 2005) and data from the US Census used in the post-stratification procedure for computing the screener survey weights (Al-Delaimy et al., 2007b).

When examining trends within specific demographic groups, the standardization procedure used the cells defined the other demographic groups within the group of interest. For instance, when examining trends by gender, the $5(\text{age}) \times 2(\text{race/ethnicity}) \times 2(\text{education}) = 20$ cells within each gender were the basis for the direct standardization procedure. For examining estimates within gender by race/ethnicity, $5(\text{age}) \times 2(\text{education}) = 10$ cells were used, etc.

Standardized Estimates of Adolescent Smoking Prevalence

The sample sizes for the adolescent survey in each year were adequate for a direct standardization procedure. Within each demographic category, the prevalence estimates were standardized for all other demographic categories. For instance, within gender, the estimates were standardized by age (12-13, 14-15, and 16-17 years) and race/ethnicity (Non Hispanic White, Hispanic, African American/Other, and Asian), and within age group, estimates were standardized by gender (male and female) and race/ethnicity. The 'other' group was combined with African Americans for computing cell fractions, but they were omitted when computing the cell prevalence for African Americans.

Volume 2, Chapter 4

MEDIA AND MARKETING INFLUENCES ON SMOKING

Two tables from this chapter use data from a large Dartmouth database of smoking in movies, courtesy of James D. Sargent. Details of the methodology are described below.

A content analysis of popular movies was conducted, including the top 100 box office “hits” per year for the years 2000 through 2005. Box office ranking based on gross revenues was determined through a site on the Internet that compiles box office data from multiple sources (<http://www.worldwideboxoffice.com>). Movie rating, total run time, and information on production companies were obtained from the Internet Movie Database (<http://www.IMDB.com>). Genre categories for the content analysis were selected after a careful review of the Internet Movie Database and several popular movie guides. When these sources listed more than one genre for a movie, the coders chose the one that best described the movie. Coded movies were viewed on DVD. Each movie was watched in its entirety at least twice in order to code the overall characteristics of the movie and to identify every occurrence of tobacco use. Each episode of tobacco use or handling was then viewed multiple times to characterize the use and its context.

Measures of Tobacco Use in Movies

A count measure (number of episodes) was used by major characters to describe tobacco exposure in movies. Major characters are those who play a leading role or who are essential to the development of the plot, and for whom the name of the actor was entered into the database. An episode consisted of using or handling any form of tobacco during a scene and delimited by the beginning and end of a scene. A scene was defined as a clear passage of time or change in location. The episode was counted without regard to the duration of tobacco use in the scene.

For example, if one character used or handled tobacco multiple times within the same scene, this was counted only as one episode. If two characters used or handled tobacco in the same scene, this was counted as two episodes. Other forms of tobacco imagery, such as billboards, signs, and ashtrays were not included, because these images were not generally associated with any major character. For the study, episodes of major characters were aggregated by actor across the movie sample frame. This resulted in a dataset for each actor, with the number of movies the actor starred in, the number of characters he/she played, the number of characters who smoked, and the number of smoking episodes attributable to the actor.

Two coders were selected and trained to conduct the content analyses. To evaluate inter-rater reliability, 10% of the movies were coded by both coders.

Favorite Anti-Smoking Advertisements

Adult and adolescent respondents were asked to describe their favorite anti-smoking advertisement. The open-ended responses were coded by a UCSD staff member. Assistance in coding the open-ended responses to favorite anti-smoking advertisement questions was received from the California Department of Health Services (Colleen Stevens) and the American Legacy Foundation (Aaron Mushro).

GLOSSARY

Adolescents

Committed never smoker – a *never smoker* who answers definitely not in answer to three questions: trying a cigarette soon, accepting a cigarette if offered by a best friend, and likelihood of smoking in the next year.

Current established smoker – an *established smoker* who has smoked a cigarette on any day in the past month.

Current experimenter – an *experimenter* who has had a cigarette in the past 30 days or admits to smoking once in awhile.

Current smoker – has smoked a cigarette on at least one day in the past month.

Established smoker – has smoked at least 100 cigarettes in his or her lifetime.

Ever smoker – has smoked a cigarette (includes *puffers*)

Experimenter – has smoked a cigarette (excludes *puffers*), but has not smoked at least 100 cigarettes in his or her lifetime.

Former smoker – an *established smoker* who has not smoked a cigarette on any days of the past month.

Never smoker – has never smoked or even puffed on a cigarette.

Non-current smoker – has not smoked a cigarette on any days in the past month.

Puffer – someone who has not smoked a whole cigarette, but admits to puffing on one.

Susceptible never smoker – a never smoker who fails to answer “definitely not” to all three questions about trying a cigarette soon, accepting a cigarette if offered by a best friend, and their likelihood of smoking in the next year.

Adults

Current experimenter – an *experimenter* who has had a cigarette in the past 30 days or admits to smoking once in awhile.

Current smoker – has smoked at least 100 cigarettes in his or her lifetime and smokes now either everyday or some days.

Daily smoker – a current smoker who has smoked on every day of the past month.

Established smoker – has smoked at least 100 cigarettes in his or her lifetime.

Ever daily, current non-daily – has smoked at least 100 cigarettes in his or her lifetime and has smoked on a daily basis for at least 6 months but now smokes only some days.

Ever smoker – has smoked at least 100 cigarettes in his or her lifetime.

Experimenter – has smoked a cigarette), but has not smoked at least 100 cigarettes in his or her lifetime.

Former smoker – has smoked at least 100 cigarettes in lifetime, but does not smoke now (old question) or now smokes not at all (new question).

Light daily smoker – a *current smoker* who now smokes ‘everyday’ and reports consuming fewer than 15 cigarettes/day.

Light smoker – a *current smoker* who smokes fewer than 15 cigarettes a day.

Moderate-to-heavy daily smoker – a *current smoker* who smokes 15 or more cigarettes a day.

Never smoker – has smoked fewer than 100 cigarettes in his or her lifetime.

Non-daily, never daily – has smoked at least 100 cigarettes in his or her lifetime but has never smoked on a daily basis for at least 6 months.

Non-daily smoker – a *current smoker* who smokes some days.

Nonsmoker – a *never smoker* or a *former smoker*.

Recent quitter – a *current smoker* with an quit attempt in the last year; a *former smoker* with a quit attempt of less than 1 year.

Smoker in the last year – Either a *current smoker* or a *former smoker* who smoked regularly a year before the survey.

Social smoker – a *current experimenter* or *non-daily smoker* who smokes only when others are smoking.
