## 1. INTRODUCTION

The 1996 Follow-on Surveys to the Initial Baseline Surveys of Attitudes, Behaviors, and Media Exposure Regarding Smoking and Tobacco Use, has utilized a random digit dialing probability sample of telephone households using the list-assisted RDD method. This method significantly reduces the cost and time involved in such surveys in comparison to dialing numbers completely at random.

The general approach employed a two-stage sampling procedure in which a sample of 39,674 households was initially selected and successfully screened to obtain information about the smoking status of all household members. At the second stage, extended interviews were attempted with all screener respondents (adults), a random sample of other adults (sampling rate was based on the smoking status), and all young person between the ages of 12 and 17.

Four different type of instruments -- Screener Survey, Short-Adult Survey, Long-Adult Survey, and Teen Survey -- were developed by UCSD and Westat for the 1996 Surveys of Attitudes, Behaviors, and Media Exposure Regarding Smoking and Tobacco Use to provide data that would be comparable to both 1992 and 1993 surveys. Details on these instruments can be found in *Description of Methodology, Volume 1: Data Collection Methodology*.

For the 1996 Survey, Westat, Inc. was responsible for some statistical tasks including sample selection, weighting, and data collection. This report contains a description of the methodology used by Westat to sample selection, weighting, and development of replicate weights for the variance estimation purposes.

## 2. SAMPLE SELECTION

Households that had at least one 18 years and older adult in California were selected for the 1996 California Tobacco Survey by a random digit dialing (RDD) procedure known as the “list-assisted” sampling method. Under the list-assisted sampling method, random samples of telephone numbers were selected from “banks” of 100 telephone numbers<sup>1</sup> that were known to contain at least one *listed* residential telephone number. Those banks with at least one listed residential telephone numbers are referred to as “1-plus working banks.”

Nationally, only 20 percent of all numbers are working residential numbers; however about 52 percent of telephone numbers in 1-plus working banks are residences (households). Use of 1-plus working banks in the list-assisted sampling approach is not without a cost, however. The “cost” is the potential bias resulting from the exclusion of some unlisted residential telephone numbers in the “zero banks<sup>2</sup>” and some residences in “new-banks<sup>3</sup>.” Fortunately, less than 4 percent of all telephone households (nationally) would be excluded from this sampling process.

The first step in the list-assisted sampling process involved identifying those area code/exchanges that had any households in the target area of interest. The process of mapping area code/exchanges into small geographical was not always straight forward because telephone exchanges straddled county boundaries. The sampling frame vendor (GENESYS) provided 18 *exchange coverage reports* containing all the exchanges that covered each of the 18 Tobacco Study Regions. There were some overlaps of exchanges among the coverage reports -- 89.2 percent of the exchanges covered single regions, 10.7 percent of the exchanges covered two regions, and 0.1 percent of the exchanges covered three or more regions. Every exchange in the coverage report was associated with a *county of plurality* (i.e., the county that had the highest percentage of listed numbers in the exchange) in the telephone numbers database provided to WESTAT by GENESYS. For sampling purposes exchanges were allocated to unique regions based on the county of plurality measure. Moreover, a few<sup>4</sup> exchanges that had very high density of pagers and other non-residential hand held devices were omitted. The GENESYS database system did not contain

---

<sup>1</sup> Specifically, each “bank” is uniquely defined as the set of 100 possible telephone numbers having the same 3-digit area code, 3-digit exchange, and next two digits of the telephone number. For example, the first eight digits of 301-251-43XX, where XX denotes any value from 00 to 99, defines a “bank.”

<sup>2</sup> Zero-bank is a working bank of 100 telephone numbers with no listed residence.

<sup>3</sup> Banks in new exchanges with no listing information at the time of the last update of the Bellcore and Donnelly databases.

<sup>4</sup> 37 exchanges (out of a total of 4,106 exchanges) that are of Bellcore Type 02, 04, 55, and 56.

these exchanges. The exchanges that were not considered for sampling purposes covered less than 1 percent of all the exchanges that contained the 1-plus working banks covering the State of California.

After identifying the exchanges for the 18 regions, these exchanges were combined with the GENESYS database to extract the exchange level demographical estimates. Development of exchange level demographical estimates are from the Spring 1996 Claritas/NPDC Update File (National Planning Data Corporation). (GENESYS semi-annually updates its database from data compiled from several sources including Bellcore Tape, Claritas/NPDC, Donnelley Quality Index Database (100 percent Phone File), United States Postal Services Tape, Rand McNally Atlas, and A. C. Nielson Co.). One of the information sources that could have been used is the number of teens (12-17 years old) covered by each exchange. GENESYS database gave the number of persons below 18 years (0-17) and it was assumed that an exchange associated with high concentration of 0 to 17 years was also associated with high concentration of 12 to 17 years old teens.

Table 2-1 contains the summary of exchange level statistics from the GENESYS database and the GENESYS Coverage Reports. Included in Table 2-1 are the estimated total households, actual listed households, estimated total population, number of persons below 18, number of persons 18 or older, working bank count, total listed households (from GENESYS coverage report), listed households in region (from GENESYS coverage report), and estimated residency rate (percentage of numbers that may be residential).

The estimated total households (Column 1) contains the households that are not covered by the 1-plus working banks. That is, it includes non-telephone and households in unlisted banks. Note that in 1990, 97 percent of the California households had telephones. Also past experience in The Women's CARE Study showed that 1.3 percent of the sampled nonworking bank numbers found to be residential in Los Angeles County<sup>5</sup>. Taking these two factors into account it is estimated that the actual households covered by the 1-plus working banks were about 96 percent of the total households. It is likely that more than 4 percent of the California households with telephones had more than one residential telephone numbers. Therefore the ratio of the GENESYS estimated total households to the total available numbers in the working banks was a fairly conservative measure (lower bound) of Residency Rate (Column 9). The overall estimated residency rate was estimated at 46.4 percent.

Imperial	18	404,184	221,238	1,223,740	396,215	827,525	8,498	222,719	222,491	47.6%	1,500	4,505	6,398
Total		11,050,867	6,390,355	30,944,479	8,127,595	22,816,884	238,009	6,595,780	6,476,742	46.4%	34,240	105,636	150,001

Based on past experience with national studies using list-assisted RDD, such as NHES, a preliminary estimate of at least 88,774 numbers (before tritone and business purge) appeared necessary. However more recent estimate indicate that at least 105,636 numbers (before tritone and business purge) are required. It was a standard practice to oversample the telephone numbers by about 50 percent and release a smaller random portion to Telephone Research Center and keep the remainder as a reserve sample. Eighteen equal probability samples within the working banks covering the 18 regions were sampled and each sample is about 50 percent bigger than the minimum sample size needed as shown in Column 12 of Table 2-1.

The cost of screening is generally proportional to the number of telephone numbers sampled and the variance of an survey estimate, such as estimated population mean or proportion, is approximately inversely proportional to the number of completes.

### 3. WEIGHTING

#### 3.1 Imputation

There are numerous reasons for item nonresponse. Some respondents do not know the answer for the item or do not wish to respond for other reasons. Some item nonresponse arises when an interview is interrupted and not continued later, leaving items at the end of the interview blank. Item nonresponse may also be encountered because responses provided by the respondent are not internally consistent and this inconsistency will not be discovered until after the interview is completed. In these cases, the items that are not internally consistent are usual set to missing (“not ascertained”) during the data editing.

Imputations are done for two reasons. First, complete responses are needed for variables used in developing the sampling weights. Second, users will be computing estimates using a variety of methods and complete responses should aid their analyses. But our primary purpose of item imputation is to develop sampling weights.

The order of imputation should be carefully planned. Certain variables are imputed first so that they could be used to create cells for weighting class adjustments and for subsequent imputation. In cases in which a sort variable within a given file has missing values for some cases, all other sort variables without missing values may be used to impute the sort variable with missing values prior to continuing with subsequent stages of imputation.

Prior to weighting, all missing values of some key demographic variables -- gender, race, age, and education -- were imputed. The imputation steps that we followed are given next.

##### 3.1.1 Imputation in Screener File

As in the past California Tobacco Studies the missing values of gender, race, age, and education in the screener file were imputed in two steps. In the first steps, all extended interview values of the above demographic variables were used to overwrite any missing data in the screener file. In the next step, using Westat’s hot-deck imputation macro, WESDECK, all remaining missing values were imputed.

### **3.1.2 Imputation in Extended Interview Files**

There are three extended interview files -- short-adult, the long-adult, and the teen interview files.

Once all missing screener weighting items have been imputed, they will be used to replace any missing value (in gender, race, age, and education) that will be encountered in any of the extended interview files.

## **3.2 Weighting Overview**

The process of weighting refers to the computation of case-specific sampling weights that are necessary for producing almost unbiased estimates of the population parameters of interest. The weights are needed in the statistical analysis to compensate the variable probabilities of inclusion in the sample. Even for samples in which units are selected with equal probabilities, weighting may still be necessary to compensate for differential rates of nonresponse and deficiencies in the sampling frame. Weighting complex survey data, such as the data from this study, generally involves many steps. The most important steps for this study are the determination of overall probabilities of selection, calculation of base weights, calculation of nonresponse adjustments, poststratification, and development replicate weights.

Computation of sampling weight components were analogous to that used for the previous CTS surveys. The weighting components consist of base weights, household weights, subsampling factors, nonresponse adjustment factors, and raking ratios.

## **3.3 Base Weights**

The base weight of a sampling unit is defined as the reciprocal of the probability of selecting that sampling unit. The base weights are unbiased in the sense that the expected value of a weighted estimate based on the sample data is equal to the corresponding population value that would have been obtained if all the units (rather than a sample) in the frame were surveyed. A noncoverage bias results because the RDD sampling methodology excludes some eligible households.

In the list-assisted RDD method, we used an equal probability of selection of telephone numbers. The base weight for a sampled telephone number is  $w = 1/f$ , where  $f$  is the overall sampling rate. If a simple random sampling scheme was used, the probability of selecting  $n$  telephone numbers from a pool of  $N$  numbers is  $f = n/N$ .

With the use of list-assisted telephone sampling frame, all telephone numbers covering a study area have the same overall probability of selection. Thus, the probability that a household with  $m$  telephone numbers will be included in the sample is simply  $fm$ , where  $f$  is the overall sampling rate for the pool of numbers generated from the working banks of 1 or more listed numbers.

About 39,674 households that had persons 18 years and older in California were successfully screened based on 150,001 telephone numbers selected by the one-plus list-assisted sampling scheme. Under this scheme, 18 equal probability samples of telephone numbers were selected from 18 sampling frames -- one per each Tobacco Region. The base weight of a sampled telephone number is the inverse of the probability of selection.

The base weight of a telephone number selected from the frame corresponding to the  $i$ -th region is given by,

$$b_i = \frac{N_i}{n_i}, i = 1, 2, \dots, 18;$$

where

$N_i$  = total number of available telephone numbers in the  $i$ -th frame; and

$n_i$  = number of telephone numbers sampled from the  $i$ -th frame.

### 3.4 Household Weights

We expected about 50 percent of the sampled numbers to be residential. Assuming that every residence had exactly one residential telephone number, then the household weight of a household is same as the base weight of the corresponding telephone number.

As in the past, households with more than one residential telephone will be assigned a weight of 1/2. A weighting factor of unity is assigned to households reporting one telephone number in the household. An adjustment factor of 1/2 is assigned to households with more than one residential telephone number<sup>6</sup>. Technically, if the other telephone number(s) of households with multiple residential telephone numbers is in the zero-listed stratum, the household should get a weight adjustment of 1. However, the practice of looking up the other phone numbers in these households is impractical and the percent of such numbers in the zero-listed stratum is small. Eventually, the  $j$ -th household in the  $i$ -th region receives a weight of:

$$h_{ij} = \begin{cases} b_i \times 0.5 & \text{If the household has more than one telephone number} \\ b_i & \text{If the household has only one telephone number} \end{cases} ;$$

where

$b_i$  = The base weight for a sampled telephone number in the region .

The household weights will be copied to all the four weighting files -- the screener file, short-extended file, long-extended file, and the teen file.

### 3.5 Person-Level Weights

As in the past CTS surveys, all the household members are enumerated. Based on the age and smoking status, a subsample of the eligible household members is selected for extended interview.

The  $k$ -th member of the  $j$ -th household in the  $i$ -th Tobacco Region is subsampled at a rate,  $r_{ijk}$  :

$$r_{ijk} = \begin{cases} 0 & \text{If the } k\text{-th member is a child (11 years or younger);} \\ 1 & \text{If the } k\text{-th member is a teen (12 to 17 years);} \\ s_k & \text{If the } k\text{-th member is an adult and screener respondent; and} \\ t_k & \text{If the } k\text{-th member is an other eligible adult.} \end{cases}$$

---

<sup>6</sup> The weight could be modified by a factor equal to the reciprocal of the number of residential telephone numbers in the household, but the adjustment by a factor of 2 is thought to be somewhat better. Massey and Botman comment on this adjustment in "Weighting Adjustments for Random Digit Dialed Surveys", in Telephone Survey Methodology, pp. 145-146.

where

$$s_k = \begin{cases} 0.9 & \text{If smoker and selected for long instrument;} \\ 0.1 & \text{If smoker and selected for short instrument;} \\ 0.13 & \text{If nonsmoker and selected for long instrument;} \quad \text{and} \\ 0.87 & \text{If nonsmoker and selected for short instrument.} \end{cases}$$

$$t_k = \begin{cases} 0.9 & \text{If smoker and selected for long instrument;} \\ 0.13 & \text{If nonsmoker and selected for long instrument;} \quad \text{and} \\ 0 & \text{Otherwise.} \end{cases}$$

Note that for weighting purposes, smokers include both current and former smokers (in the last 5 years); nonsmokers are the people who never smoked or long-term quitters (5 or more years abstinence).

The person-level weights are constructed for all the eligible household members. The person-level base weight of the  $k$ -th member of the  $j$ -th household in the  $i$ -th region is  $w_{ijk}$ , where

$$w_{ijk} = \begin{cases} 0 & \text{If } r_{ijk} = 0; \text{ and} \\ h_{ij} / r_{ijk} & \text{If } r_{ijk} > 0. \end{cases}$$

#### 4. RATIO ADJUSTMENT (RAKING)

Theoretically, if the sample was strictly obtained by a probabilistic scheme and there is no nonresponse, then the total of the sample weights should be the population total. But in practice, this is not so due to many factors. Two important factors that contribute to the deviation of weights are nonresponse and noncoverage due to sampling only telephone households covered by selected telephone exchanges. The nonresponse and noncoverage could be reduced by forcing the weights to known population totals. This technique is called poststratification and it is a popular estimation procedure in which the weights of the respondents are adjusted so that the sum of the adjusted weights are equal to known population totals.

Since poststratification involves adjusting the weights of the respondents, the poststratified estimates are different than the estimates produced without poststratification and the variances of the estimates are also different. Poststratification is often used to reduce the variance of the estimates. Since poststratification is used so frequently and it affects the estimates and their precision, a facility for poststratifying weights has been generally incorporated in software, that analyze complex survey data, such as WesVarPC (available for free<sup>7</sup> from Westat).

Indexing the cell identifiers by  $c$ , where  $c=1, \dots, L$  (for example region by the age by gender cells), the weights were first summed by cell

$$\hat{W}_c = \sum_{i \in c} w_i,$$

where  $w_i$  was the weight of the respondent  $i$  that fell in cell  $c$ .

Next, the multiplicative poststratification adjustment factor for cell  $c$  was computed as

$$A_c = \frac{N_c}{\hat{W}_c},$$

where  $N_c$  was the control total for cell  $c$ .

---

<sup>7</sup> To obtain a copy of WesVarPC and documentation, visit the Westat's Web-site <http://www.westat.com>.

The poststratified weight was the weight multiplied by the poststratification adjustment factor corresponding to the correct cell

$$PW_i(c) = A_c w_i \text{ for } i \in c.$$

Raking ratio estimation, or simply raking, can be considered as poststratification performed iteratively in order to control two (or more) known marginal population totals. Raking was first proposed by Deming and Stephan (1940) as a way of assuring consistency between complete count and sample data from the 1940 U.S. Census of Population. Typically, raking is used in situations where the interior cells of a cross tabulation are either unknown, or some sample sizes in the cells are too small for efficient estimation. Oh and Scheuren (1987) provide a concise description of the raking procedure and its properties.

In raking, the marginal population totals,  $N_i$  and  $N_j$  are known (say, age and sex population counts), however, the interior cells of the cross-tabulation  $N_{ij}$  (the age by sex cells) are estimated from the sample by  $\hat{N}_{ij}$ , where these are the sum of the weights in the cells. The raking algorithm proceeds by proportionately scaling the  $\hat{N}_{ij}$ , such that the following relations are satisfied:

$$\sum_j \hat{N}_{ij} = N_i,$$

and

$$\sum_i \hat{N}_{ij} = N_j.$$

It has been shown (e.g., Ireland and Kullback, 1968) that, under some regularity conditions if only the  $N_i$  and  $N_j$  are known, then the estimates,  $\hat{N}_{ij}$ , obtained by raking to convergence are asymptotically unbiased, normally distributed and minimum variance.

The person-level weights were raked to recent California population counts. The needed controls are presented in Tables 4-1 through 4-8.

Table 4-1. Population estimates by region and gender (1=male and 2=female) for the screener file

Region	Gender	Population*
1	1	4,651,639

#### 4.1 Screener Sample

All screened householders were assigned their household-level weights,  $h_{ij}$ . These base weights then were raked in two dimensions. The first dimension was defined by region and gender, while the second was defined by race (Hispanic, white, black, and other), age (0-11, 12-17, 18-24, 25-44, and 45+), and education (0-11, 12, and 13+). Tables 4-1 and 4-2 contain the needed control counts.

#### 4.2 Teen Sample

For the Teen file, three raking dimensions were used. The first dimension was defined by region and gender, the second was defined by race and age (12-14, 15-17), and the third dimension was defined by race, education and status of the head of the household. The population estimates for the latter dimension will be obtained from the weighed screener data. Tables 4-3, 4-4, and 4-5 contain the needed control counts.

#### 4.3 Short-Adult Sample

It was desired to compare the weighted short-adult data to the 1993 adult data. Therefore, it was necessary to follow the same steps as in 1993. The person-level nonresponse adjusted weight was

raked in two dimensions. The first dimension was defined by region and gender, while the second dimension was defined by race and age. The needed control counts are presented in Tables 4-6 and 4-7.

On UCSD’s request the short-adult data weights were modified to include all the screener respondents in the raking step. That is, the weights of all the screener respondents (some completed Short-Adult Survey and others completed Long-Adult Survey) were raked to the appropriate control totals described earlier.

#### 4.4 Long-Adult Sample

It was desired to compare the weighted long-adult data to the 1992 adult data. In 1992, the weights that were delivered to UCSD by Westat were eventually modified for analysis and for the purpose of a Public Use Tape. Therefore, Westat statisticians attempted to weight the long-adult data such that it would be comparable to the 1992 Public Use Tape. The person-level nonresponse adjusted weight was raked in five dimensions. The first and second dimensions were the same as that of the short-adult sample described in Section 4.3. The third, fourth, and fifth dimensions involved smoking status and the various distributions of adult smoking status by education, gender, and age were derived from the weighted screener data. The desired control totals for these dimensions are described in Tables 4-8, 4-9, and 4-11.

Table 4-9. Population estimates by smoking status and gender (1=male and 2=female) for the long-adult file

## 5. VARIANCE ESTIMATION

When data are collected as part of a complex sample survey, there is often no easy way to produce approximately unbiased and design-consistent estimates of variance analytically. The variance of survey statistics, including means and proportions, estimated using standard statistical packages such as SAS or SPSS, are inappropriate and usually too small. A class of techniques called *replication methods* provides a general method of estimating variances for the types of complex sample designs and weighting procedures usually encountered in practice. The basic idea behind the replication approach is to select subsamples repeatedly from the whole sample, to calculate the statistic of interest for each of these subsamples, and then to use the variability among these subsample or replicate statistics to estimate the variance of the full sample statistics. There are different ways of creating subsamples from the full sample. The subsamples are called *replicates* and the statistics calculated from these replicates are called *replicate estimates*.

Replication is not the only way to compute the variance of statistics from complex samples; however, it is able to handle complex sampling designs, complex estimates, and complex weighting schemes. Replication can be used where other methods are not easily applicable. This method also has some advantages even when other methods, such as Taylor series approximation, can be applied

One of the main advantages of the replication approach is its ease of use at the analysis stage. The same estimation procedure is used for the full sample and for each replicate. The variance estimates are then readily computed by a simple procedure. Furthermore, the same procedure is applicable to most statistics desired such as means, percentages, ratios, correlation, and so forth. These estimates can also be calculated for analytic groups or subpopulations. It is not even necessary for the analyst to understand the sampling or estimation methods if the replicate weights are included with the data.

Analogous to the previous studies, for the 1996 CTS survey the jackknife method of replication was used for estimation of sampling errors. This method employs the full sample estimate,  $\hat{q}$ , and replicate estimates,  $\hat{q}_r$ , ( $r = 1, \dots, R$ ) for a parameter of interest,  $q$ , to estimate the sampling error of  $\hat{q}$  using the following estimator:

$$v(\hat{q}) = \frac{R-1}{R} \sum_{r=1}^R (\hat{q}_r - \hat{q})^2.$$

In order to remain consistent with the replicate structure of the previous CTS surveys, a set of 51 replicate groups was generated. The data file was first sorted according to the 18 regions and then assigned to the replicate groups based on the order of sample (telephone number) selection. The calculation of replicate weights proceeded as follows.

First, each of the screened householders were assigned their final person-level base weights in each of the 51 replicate groups. In the next step, replicate base weights were adjusted to reflect the deletion of that portion of the sample which was excluded for formation of respective replicates (i.e., the full sample base weight of all nondeleted units in each replicate were multiplied by 51/50). Each of the resulting 51 sets of replicate base weights were then raked to the same control counts used for raking of the full sample weights.

## 1996 California Tobacco Survey

### **INDIVIDUAL ITEM RESPONSES**

#### **7.1 Screener File**

To read Sections 7.1 through 7.4 on your monitor, you may need to increase the magnification (zoom) level by doing one of the following:

- (1) Go to the magnification tool button located in the lower left corner of your open document, then select the zoom level.
- (2) Go to the View menu, select Zoom to, then select the zoom level.

If printed, these sections will be readable.

Individual Item Responses: Screener File

## 1996 California Tobacco Survey

### **INDIVIDUAL ITEM RESPONSES**

#### **7.2 Adult Short Interview File**

To read Sections 7.1 through 7.4 on your monitor, you may need to increase the magnification (zoom) level by doing one of the following:

- (1) Go to the magnification tool button located in the lower left corner of your open document, then select the zoom level.
- (2) Go to the View menu, select Zoom to, then select the zoom level.

If printed, these sections will be readable.

## 1996 California Tobacco Survey

### **INDIVIDUAL ITEM RESPONSES**

#### **7.3 Adult Extended Interview File**

To read Sections 7.1 through 7.4 on your monitor, you may need to increase the magnification (zoom) level by doing one of the following:

- (1) Go to the magnification tool button located in the lower left corner of your open document, then select the zoom level.
- (2) Go to the View menu, select Zoom to, then select the zoom level.

If printed, these sections will be readable.

Individual Item Responses: Adult Extended Interview File

## 1996 California Tobacco Survey

### **INDIVIDUAL ITEM RESPONSES**

#### **7.4 Teen Extended Interview File**

To read Sections 7.1 through 7.4 on your monitor, you may need to increase the magnification (zoom) level by doing one of the following:

- (1) Go to the magnification tool button located in the lower left corner of your open document, then select the zoom level.
- (2) Go to the View menu, select Zoom to, then select the zoom level.

If printed, these sections will be readable.
